ABSTRACT

Competitive programming problems increasingly serve as valuable benchmarks to evaluate the coding capabilities of large language models (LLMs) due to their complexity and ease of verification. Yet, current coding benchmarks face limitations such as lack of exceptionally challenging problems, insufficient test case coverage, reliance on online platform APIs that limit accessibility. To address these issues, we introduce LiveOIBench, a comprehensive benchmark featuring 403 expert-curated Olympiad-level competitive programming problems, each with an average of 60 expert-designed test cases. The problems are sourced directly from 72 official Informatics Olympiads in different regions conducted between 2023 and 2025. LiveOIBench distinguishes itself through four key features: (1) meticulously curated high-quality tasks with detailed subtask rubrics and extensive private test cases; (2) direct integration of elite contestant performance data to enable informative comparison against top-performing humans; (3) planned continuous, contamination-free updates from newly released Olympiad problems; and (4) a self-contained evaluation system facilitating offline and easy-to-reproduce assessments. Benchmarking 32 popular general-purpose and reasoning LLMs, we find that GPT-5 achieves a notable 81.76th percentile, a strong result that nonetheless falls short of top human contestant performance, who usually place above 90th. In contrast, among open-weight reasoning models, GPT-OSS-120B achieves only a 60th percentile, underscoring significant capability disparities from frontier closed models. Detailed analyses indicate that robust reasoning models prioritize precise problem analysis over excessive exploration, suggesting future models should emphasize structured analysis and minimize unnecessary exploration. All data, code, and leaderboard results will be made publicly available on our website.

1 Introduction

Coding has emerged as a critical domain for LLMs (Zhuo et al., 2024; Lai et al., 2022; Liu et al., 2024; Jimenez et al., 2024; Chan et al., 2024), with coding benchmarks serving as essential tools to evaluate LLMs' algorithmic reasoning capabilities as these models continue advancing through inference-time scaling techniques (Li et al., 2022a; Kojima et al., 2023; DeepSeek-AI et al., 2025; OpenAI et al., 2024; Li et al., 2025b). However, rapid improvements in model capabilities have led to saturation of traditional coding benchmarks such as HumanEval (Chen et al., 2021) and MBPP (Austin et al., 2021), prompting the adoption of competitive coding benchmarks (Li et al., 2022a; Hendrycks et al., 2021b; Li et al., 2023; Shi et al., 2024) such as LiveCodeBench (Jain et al., 2024) and CodeELO (Quan et al., 2025), which leverage problems from platforms like Codeforces for their complexity

^{*}Correspondence to zkjzou@umich.edu

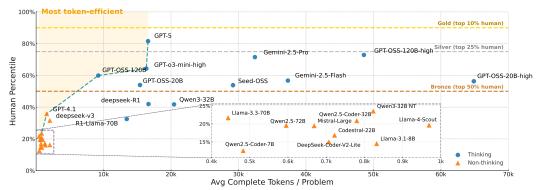

Figure 1: **LiveOIBench.** Average human percentile across all contests versus average completion tokens per problem. The dashed boxes highlight the lower performance range of non-thinking LLMs. OpenAI models lie on the token-efficiency frontier, achieving higher human percentile with fewer tokens. Despite improvements, all evaluated models remain below the Gold medal threshold (top 10% human performance), indicating substantial room for progress.

and ease of verification. Despite their strengths, these benchmarks have notable weaknesses: (1) overestimation of LLMs' performance due to high false-positive rates using incomplete test suites (Li et al., 2022a; Liu et al., 2023; Jain et al., 2024), (2) insufficient difficulty granularity and lacking exceptionally challenging questions (Jain et al., 2024; Quan et al., 2025), (3) usage of external APIs for evaluation, restricting reproducibility and accessibility (Jain et al., 2024; Quan et al., 2025; Zheng et al., 2025; Li et al., 2025c), (4) reliance on coarse pass rates as the sole evaluation metric, which misses the opportunity to gain insights on nuanced model capabilities (Jain et al., 2024; Li et al., 2022a; Wang et al., 2025; Shi et al., 2024), and (5) infrequent or costly updates due to the extensive human annotations and computational resources required (Wang et al., 2025; Zhu et al., 2025).

To address these gaps, we introduce LiveOIBench, the first comprehensive competitive coding benchmark constructed directly from Informatics Olympiads tasks, featuring expert-designed private tests, which will be made publicly available to support reproducible evaluation along with fine-grained scoring rubrics. Compared to previous benchmarks (Jain et al., 2024; Shi et al., 2024; Hendrycks et al., 2021b; Li et al., 2022a; Quan et al., 2025) and concurrent work (Li et al., 2025c; Zheng et al., 2025; Zhu et al., 2025; Wang et al., 2025) in Table 1, LiveOIBench features the following key advancements:

- 1. Expert-curated Tasks with Fine-grained Subtask Rubrics. We curate problems, test cases, and scoring rubrics directly from the official websites of 14 Informatics Olympiads. This comprehensive test suite eliminates high false-positive rates common in previous benchmarks (Li et al., 2022a; Liu et al., 2023; Jain et al., 2024). Additionally, each task includes subtasks with scoring rubrics, enabling nuanced insights into model capabilities.
- Direct Human Contestant Comparisons. Official results from top human competitors are collected, allowing direct and informative benchmarking against human-level performance.
- 3. **Continuous, Contamination-free Updates.** Updates with newly released Olympiad tasks maintain benchmark freshness and minimize data contamination risks, supporting continuous monitoring of LLM coding capabilities on challenging programming problems.
- 4. **Integrated Offline Evaluation System.** We develop a self-contained evaluation judge, enabling fully offline and reproducible model evaluation without relying on external APIs or online platforms, significantly enhancing accessibility and reproducibility.

In total, LiveOIBench comprises 403 rigorously curated problems sourced from 72 contests across 14 Informatics Olympiads, each accompanied by an average of 60 expert-written test cases. Using LiveOIBench, we evaluate 32 leading models, revealing that proprietary models maintain a substantial performance advantage. In particular, GPT-5 (OpenAI, 2025b) achieves an average human percentile of 82, while also exhibiting remarkable token efficiency by reaching this performance with fewer than 20K reasoning tokens, positioning it on the efficiency frontier (Figure 1). Among open-weight alternatives, Seed-OSS (ByteDance Seed Team, 2025) achieves the 54th percentile and Qwen3-32B (Yang et al., 2025b) reaches the 42nd percentile, both demonstrating significant performance gains

Table 1: Comparison with existing coding datasets. LiveOIBench consists of continuously updated competitive coding problems from recent Informatics Olympiads, spanning various difficulty levels. Unlike previous benchmarks that generated test cases using predefined rules or LLMs, LiveOIBench features expert-curated *private* test cases sourced *directly* from official competition organizers. It also provides an accessible *offline* evaluation platform, detailed subtask rubrics for *fine-grained* assessment, and official human contestant rankings for precise *human-model* comparisons.

from additional reasoning tokens. Additionally, GPT-OSS-120B (OpenAI et al., 2025) attains the 60th percentile, effectively narrowing the performance gap with GPT-5 and highlighting significant progress in open-weight model capabilities. Moreover, examining performance across different algorithms reveals current models' weaknesses in algorithms like dynamic programming, which demand creative observation and hierarchical reasoning. Additionally, detailed reasoning trace analyses reveal that high-performing models strategically allocate more tokens to focused analysis rather than excessive exploration, underscoring that carefully managed reasoning behaviors are crucial for robust performance on challenging tasks.

In summary, we make the following key contributions:

- (**Data**) Curate and release a comprehensive, high-quality competitive coding benchmark with expert-crafted problems, hidden test suites, and integrated human contestant results.
- (Evaluation) Provide a robust local evaluation framework with private test cases and detailed subtask scoring rubrics, enabling accessible, fine-grained human-model comparisons.
- (Benchmarking Results) Conduct extensive benchmarking and detailed performance analysis of 32 leading open-source and proprietary models.
- (Analyses) Perform extensive analyses such as evaluating model performance across diverse algorithms, detailed reasoning trace analyses, examination of solution submission outcomes, and assessments of model performance under inference-time scaling.

2 Related Work

The early code generation benchmarks such as HumanEval (Chen et al., 2021) and MBPP (Austin et al., 2021) mainly focus on the basic Python programs, which, for a long time, have been the standard ways to evaluate the code generation capability of LLMs. However, as the capability of LLMs evolves, simple benchmarks like HumanEval can no longer satisfy the benchmarking needs. Researchers have started developing more realistic and challenging benchmarks (Zhuo et al., 2024; Lai et al., 2022; Liu et al., 2024; Jimenez et al., 2024; Chan et al., 2024; Yin et al., 2023). Specifically, DS1000 (Lai et al., 2022) and ARCADE (Yin et al., 2023) consist of data science problems in Python. BigCodeBench (Zhuo et al., 2024) collects code generation tasks from Stack Overflow, which involves more complex instructions and diverse function calls. The SWE-Bench (Jimenez et al., 2024) takes one step further and tests models' ability to solve real-world GitHub issues. This line of work emphasizes evaluating LLMs' ability to effectively implement, debug, and reason through complex real-world coding tasks.

In addition to real-world application benchmarks, there is another line of work: **competitive programming benchmarks** (Li et al., 2022a; Hendrycks et al., 2021b; Jain et al., 2024; Quan et al., 2025), which test the reasoning ability of models to solve challenging coding tasks within the specified time and memory constraints. All the previous competitive programming benchmarks

collect problems from online coding platforms such as Codeforces and AtCoder, which do not release private test cases. The lack of sufficient private test cases may cause many false-positive solutions (Li et al., 2022a; Liu et al., 2023). Li et al. (2022a) augment test cases by mutating existing test inputs. Liu et al. (2023) leverages both LLM-based and mutation-based strategies to augment test cases with predefined rules. Even with over 200 additional tests per problem, Li et al. (2022a) shows there still exists nearly 50% false-positive rates. Other work (Quan et al., 2025; Zheng et al., 2025; Li et al., 2025c) tries to solve this problem by creating a platform to submit LLM-generated solutions directly to the Codeforces platform. Although this approach ensures that solutions are tested on the whole test set, its dependency on the online platform limits its accessibility to the research community, as large-scale evaluations involving thousands of submissions can overload platform servers.

To solve the above problem, we collect problems from the official websites of many informatics Olympiads around the world. Most informatics Olympiads release their complete test set, which is curated carefully by the organizing committees. We are one of the first works to leverage problems from different informatics Olympiads and evaluate the models' performance against human contestants. Prior research by Shi et al. (2024) exclusively used USACO problems with pass rate as the sole evaluation metric. Concurrent benchmarks, such as LiveCodeBench Pro (Zheng et al., 2025), HLCE (Li et al., 2025c), OI-Bench (Zhu et al., 2025), and AetherCode (Wang et al., 2025), also incorporate competitive programming tasks from sources like ICPC and IOI. However, LiveCodeBench Pro and HLCE primarily evaluate using Codeforces, limiting their accessibility. OI-Bench relies mostly on private, non-English school contests without continuous updates, while AetherCode uses LLM-generated tests and extensive human annotation with pass rate evaluation only. In contrast, our benchmark provides comprehensive coverage across diverse Olympiads, allows easy updates by directly collecting official test cases, and employs detailed evaluation metrics including subtask rubrics and human percentile comparisons.

3 LIVEOIBENCH CONSTRUCTION

To construct LiveOIBench, we follow a clearly defined, step-by-step process combining automated data collection methods with manual verification to ensure dataset quality.

Competition Selection and Task Collection: We first curate a comprehensive list of globally recognized international Informatics Olympiads and selectively incorporate national contests from top-performing IOI countries where English task statements are available (See Table A5). For each selected contest, we develop a custom crawler that systematically extracts English task statements (See Appendix A.5) directly from official competition websites, capturing details such as time and memory constraints, subtask specifications, test cases, official solutions, and contestant rankings. When official sites lack complete or up-to-date information, we supplement the data by retrieving missing details from established online platforms such as CSES¹ and LibreOJ². To mitigate potential contamination from pre-training datasets, we strictly limit our dataset to contests held in 2023 and after. Additionally, we provide full descriptions of each competition along with official websites in Appendix A.6, ensuring selected contests have extensive historical data, consistent participant numbers, and regularly hosted events. Our benchmark will be continuously updated by leveraging monthly or annual problem releases from 14 actively maintained competition websites, allowing us to regularly expand our dataset with new contests and maintain an active leaderboard using a website similar to Figure A1.

Markdown Conversion and Quality Assurance: Given that many contests provide task statements exclusively as PDF documents, we employ Marker³ to automatically convert these PDFs into markdown format. We further utilize Gemini-2.0-Flash to automatically verify and correct these markdown texts. To ensure conversion accuracy, we manually inspect a sample of 40 tasks before batch processing. Additionally, we verify our evaluation judge and crawled test cases by executing the official solutions from contest organizers, using these solutions as the ground truth to confirm test-case correctness and the robustness of our evaluation judge.

¹https://cses.fi

²https://loj.ac

³https://github.com/datalab-to/marker

Metadata Enrichment: We enhance the dataset with supplementary metadata, including difficulty and algorithm tags such as dynamic programming and greedy, crawled from solved.ac⁴ and Luogu⁵. Tasks and metadata are matched using competition dates, task titles, and problem identifiers. More details can be found in Appendix A.3.

Contestant Matching and Codeforces Ratings: Beyond raw human contestant results, contestants are automatically linked to their respective Codeforces profiles based on their names, user IDs, and countries, while contestants whose profiles cannot be confidently matched are skipped. Verified profiles are then queried via the Codeforces API to retrieve user ratings from 2022 to 2025. More details can be found in Appendix A.4 and Table A6.

Ultimately, LiveOIBench comprises 403 **rigorously curated problems** from 72 **competitions** across 14 **Informatics Olympiads**, conducted between 2023 and 2025. The benchmark statistics are detailed in Table A4, with a detailed description of our dataset construction methodology provided in Appendix A and competition information in Appendix A.6.

There are four characteristics that make our dataset challenging and unique compared to the existing coding datasets:

- Challenging Problems with Subtasks. Expert-curated problems contain subtasks with distinct constraints, enabling precise evaluation through partial scoring.
- Expert-Designed Private Tests. Includes expert-designed private tests rather than test cases generated by predefined rules or LLMs, ensuring evaluation free of false positives.
- **Direct Human Comparisons.** Benchmarks LLM performance against human contestants using percentile ranks, medals, and Codeforces ELO ratings.
- Live Updates. Continuously updated with recent contests to minimize data contamination. All 14 competitions described in Appendix A.6 in our benchmark will be updated.

4 BENCHMARKING RESULTS

We evaluate a comprehensive set of 32 LLMs. These models are categorized into three groups based on their accessibility and "thinking" capabilities: proprietary LLMs, open-weight thinking LLMs, and open-weight non-thinking LLMs. More details about models can be found Appendix B. During inference, we sample 8 candidate solutions per model and pick the solution with the highest score (Jain et al., 2024; Quan et al., 2025). We adopt the following evaluation metrics: pass rate (Kulal et al., 2019; Chen et al., 2021), relative score, human percentile, Olympics medal system, and Codeforces Elo (Quan et al., 2025; Zheng et al., 2025). With subtask rubrics and human contestants results, we can calculate each model's total points in a contest, allowing precise comparisons to human contestants via percentile rankings and medal awards. The description of each metric can be found in Table 2 or Appendix C. In Table 2, we present benchmarking results for selected models that obtain the top performance in the corresponding categories of models. Full results for all evaluated models are included in Table A9.

Proprietary LLMs remain dominant, yet open-weight models are narrowing the performance gap. Our findings indicate that proprietary LLMs continue to lead in competitive coding benchmarks. Specifically, GPT-5 achieves impressive results, securing gold medals in 50% of contests, winning medals of any type in 88.89% of contests, and outperforming an average of 81.76% of human contestants. Among open-source models tested, GPT-OSS-120B emerges as the strongest competitor. Under standard reasoning effort, GPT-OSS-120B achieves gold medals in 29.17% of contests and performs near the 60th percentile—approximately 21.86 percentile points below GPT-5. Notably, with high reasoning effort, GPT-OSS-120B surpasses Gemini-2.5-Pro and trails GPT-5 by merely 9 percentile points. Seed-OSS, the second-best open-source model, attains the 54th percentile, narrowly trailing Gemini-2.5-Flash by only 3 percentile points. However, other models exhibit substantial performance gaps, with Qwen3-32B and Deepseek-R1 obtaining gold medals in only 10% and 7% of contests, respectively, and performing at roughly the 42nd percentile. Smaller and less powerful models, such as Qwen3-4B and DeepSeek-R1-Distill-Llama-8B, exhibit notably

Qwen3-32B-Non-Thinking	1.39	16.67	12.92	24.64	8.78	1040			

Table 2: Main results of best-performing models in each category evaluated on all 72 contests. Full results for all 32 models are presented in Table A9. **Gold** and **Medals**: % of contests in which a model achieved a gold medal or any medal, respectively. **Relative Score**: % of total contest points obtained by the model. **Human Percentile**: % of human contestants that a model surpasses. **Pass Rate**: % of tasks where a model successfully passes all test cases. **Elo**: the Codeforces Elo rating earned by a model based on performance relative to human contestants. Higher is better for all metrics. Notably, the highest-performing GPT-5 achieves an impressive 81.76th percentile but still falls short of top human contestants, successfully solving only 63% of tasks in the benchmark.

lower performance—Qwen3-4B secures gold medals in only 1.39% of contests, while DeepSeek-R1-Distill-Llama-8B achieves no gold medals and ranks merely at the 3rd percentile. These results clearly demonstrate that achieving meaningful performance on competitive programming tasks in LiveOIBench requires LLMs with substantial reasoning capabilities.

Even the leading GPT-5 model falls short of top-tier human contestants. Achieving a gold medal in every contest requires consistently surpassing the 90th percentile. Although GPT-5 demonstrates remarkable capabilities with a near 82nd percentile and a rating of 2414, its performance still lags behind elite human competitors. This highlights an ongoing challenge for LLMs in surpassing human expertise in competitive coding.

Thinking models perform significantly better than non-thinking models. Models lacking extended thinking capabilities perform notably worse in our benchmark. GPT-4.1, the highest-performing non-thinking model evaluated, achieves results comparable only to Qwen3-14B.

Apart from GPT-4.1 and Deepseek-V3, all other non-thinking models fail to exceed a 10% pass rate, underscoring the critical importance of extended thinking in addressing complex competitive coding tasks. Extending this analysis, we investigate inference-time scaling techniques and find that both parallel (Chen et al., 2021; Jain et al., 2024) and sequential (DeepSeek-AI et al., 2025; Snell et al., 2024; Li et al., 2025a) scaling methods significantly enhance coding capabilities. In Figure 2, parallel scaling identifies maximum coding capacity but shows diminishing returns beyond a few attempts. While sequential scaling, by increasing the reasoning budget, allows smaller models to approach larger-model performance in Figure A4, reinforcing our earlier observation on the importance of extended thinking capabilities. For detailed analyses, see Appendix E.2.

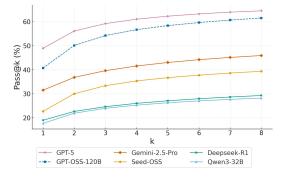

Figure 2: **Parallel Scaling** displays the Pass@k performance, illustrating how the success rate improves as more solutions (k) are sampled per problem. GPT-5 shows the highest sample efficiency and overall performance ceiling.

Table 3: Pass@8 of top-15 algorithm tags for selected models. Full results can be found in Table A10. Abbreviations: IM (implementation), MA (mathematics), AH (ad-hoc), PS (prefix sum), SO (sorting), GR (greedy), GTR (graph traversal), BS (binary search), NT (number theory), GT (graph theory), DS (data structures), CB (combinatorics), DP (dynamic programming), TR (tree), ST (segment tree). Darker color indicates the model performs better on this particular tag compared to other tags. Models generally perform better on algorithm tags that involve straightforward application of standard formulas or well-known patterns.

Comprehensive evaluation metrics provide deeper insights into model capabilities. Relying solely on pass rate can obscure key aspects of model performance. For example, GPT-OSS-120B achieves a higher pass rate (47.78%) compared to Gemini-2.5-Pro (44.46%); however, Gemini-2.5-Pro consistently surpasses GPT-OSS-120B in both human percentile ranking and ELO rating, indicating stronger overall competitive coding proficiency. We recommend that practitioners and researchers adopt a multifaceted evaluation approach: use Gold and Medals to gauge contest-level success, Human Percentile to contextualize model performance relative to humans, ELO to assess coding skill within the broader competitive coding community, and Pass Rate to evaluate core problem-solving capability. Utilizing these metrics collectively ensures a balanced and comprehensive understanding of model strengths and limitations.

Later subtasks are more challenging. We investigate how model performance is affected by the sequential position of subtasks within problems. Specifically, we segment all subtasks into five equal bins based on their relative positions and observe a consistent decline in model performance for subtasks appearing later in the sequence, as illustrated in Figure A2. This result is intuitive, as earlier subtasks typically impose stronger constraints on input variables, making them easier and prerequisites for subsequent subtasks. In contrast, later subtasks usually lack explicit constraints, requiring more generalized and optimized solutions.

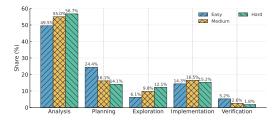

No evidence of temporal performance degradation. We examine the quarterly pass rates for four leading LLMs from Q1'23 through Q2'25 in Figure A3. Our analysis reveals no significant performance degradation coinciding with the models' knowledge cutoffs, nor any signs of benchmark contamination. A more comprehensive analysis is provided in Appendix E.1.

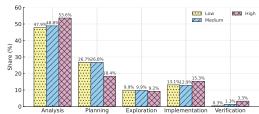

5 In-Depth Analyses of Model Behavior and Error Patterns

We first analyze algorithmic complexity to identify models' strengths and weaknesses, then explore their strategic reasoning behaviors, and finally investigate specific error patterns to pinpoint areas for model improvement.

5.1 ALGORITHMIC COMPLEXITY DETERMINES MODEL PERFORMANCE PATTERNS

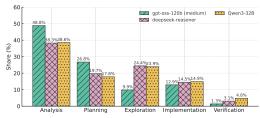

Models are generally proficient at algorithm tags that require basic mathematical procedures and minimal compositional reasoning. As shown in Table 3, all evaluated models consistently achieve higher pass rates on tasks categorized under implementation, mathematics, prefix sum, sorting, and graph traversal—GPT-5 notably attains over 70% accuracy on most of these tags. Such tasks primarily depend on recognizing familiar solution templates or leveraging procedural knowledge obtained from training. Performance noticeably declines for algorithms demanding deeper analytical

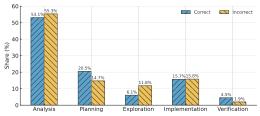

As problem difficulty increases, models prioritize exploration and analysis over planning and verification.

(c) Model comparison. Stronger reasoning models reduce unnecessary exploration, dedicating more resources to planning, structured analysis, and solution development.

(d) GPT-OSS-120B-high across correct/incorrect. Correct solutions depend heavily on initial structured planning and verification, reducing the need for exploration and continuous re-analysis.

Figure 3: Reasoning Trace Analyses. We categorized eight reasoning behaviors and divide them into five groups: Analysis (Algorithm/Proof analysis and Complexity Analysis), Planning (Problem Restatement and Subgoal Setting), Exploration (Backtracking and Dead-end recognition), Implementation (Pseudo implementation), Verification (Test Case Verification).

reasoning or succinct proofs, such as greedy methods and graph theory, where even top proprietary models like GPT-5 drop to around 60%. The greatest difficulties arise in tasks that require on-thespot creative observations, intricate state designs, or hierarchical invariants—particularly evident in dynamic programming (DP), segment trees (ST), and tree (TR) problems, where GPT-5's pass rate sharply decreases to approximately 47%, 56%, and 38%, respectively. To address these weaknesses, future work could explore curriculum-driven fine-tuning (Huang et al., 2025) using carefully designed synthetic datasets of complex graph, tree, and DP problems, encouraging models to internalize the recurrence relations, hierarchical invariants, and compositional reasoning patterns crucial to solving these more challenging algorithmic tasks.

5.2 Reasoning Trace Analyses: Stronger Models Allocate Reasoning Tokens MORE STRATEGICALLY

To better understand how thinking models solve challenging competitive coding problems, we conduct a detailed analysis on models' reasoning traces. Inspired by prior work (Gandhi et al., 2025; Ahmad et al., 2025) on reasoning behavior analysis, we categorize models' reasoning traces into eight behaviors and classify them into five groups as shown in Figure 3. Each trace is segmented into shorter chunks and annotated using GPT-OSS-120B. More details on the annotation prompt and implementation can be found in Appendix E.3.

GPT-OSS-120B increases exploration and analysis with problem difficulty, yet maintains stable exploration levels across reasoning budgets. In Figure 3a, on more challenging problems, GPT-OSS-120B-High devotes significantly more effort to exploration—searching for viable solution paths—and deeper problem analysis, simultaneously reducing the tokens spent on initial planning and verification. This indicates that initial problem structuring behaviors are typically conducted early and not revisited extensively once a potential solution path is identified. Notably, even when provided with increased reasoning budgets (from low to high reasoning effort), as shown in Figure 3b, GPT-OSS-120B strategically allocates extra tokens toward analysis, implementation, and verification, rather than further exploration. By maintaining stable exploration levels despite increased reasoning resources, the model mitigates excessive pivoting, a critical behavior that could otherwise lead to inefficient or incomplete reasoning traces, or "underthink" (Shojaee et al., 2025).

Stronger reasoning models exhibit reduced exploration, allocating more resources toward solution development and analysis. After problem difficulty and reasoning efforts, we further see, in Figure 3c and Figure A8, more capable models dedicate more reasoning tokens to problem understanding, structured planning, and detailed algorithmic analysis. Consequently, they spend less time pivoting to alternative paths, generating pseudo-implementations, or performing test-case verification. It highlights the future direction of effectively allocating models' problem analysis and exploration to avoid excessive pivoting and prevent "underthinking".

Initial planning behaviors and subsequent verification steps play crucial roles in models producing correct solutions. Building upon this observation, we also investigate which reasoning behaviors distinguish correct from incorrect solutions. As illustrated in Figure 3d, correct solutions exhibit increased planning behaviors, potentially explaining why exploration behaviors diminish—well-structured planning facilitates clearly defined solution paths, reducing the need for exploratory detours. Additionally, correct solutions engage in verification behaviors more frequently, ensuring adequate solution checks. This increased verification slightly reduces the need for extensive analysis, as models rely less on continuous reevaluation once confident in their solution correctness. Notably, correct solutions include more verification because targeted end-checks consolidate successful trajectories; however, stronger models rely less on explicit verification overall due to robust upfront analysis and planning, which internalize many checks and reduce the need for post-hoc verification.

Based on these insights, an important direction for future research is to optimize how models allocate reasoning effort across different cognitive behaviors. Specifically, exploring methods that strategically guide model attention toward structured initial planning and in-depth analysis—while carefully balancing exploration to prevent excessive pivoting—could substantially enhance both solution correctness and reasoning efficiency. Additionally, developing mechanisms that help models internalize verification during planning and analysis phases could reduce their dependence on explicit, post-hoc verification steps. Finally, creating automated techniques to dynamically adjust reasoning budgets and behaviors according to problem-specific factors like difficulty and algorithms may further boost the effectiveness of reasoning models in solving complex competitive programming tasks.

5.3 ERROR PATTERNS IN MODEL-GENERATED CODE SUBMISSIONS

Stronger reasoning capabilities in models correlate with reduced failure rates, yet runtime errors remain a notable challenge. In Figure 4, we analyze the submission status distribution across six selected models to better understand LLMs' solutions and their associated error patterns.

As models exhibit stronger reasoning capabilities, their solutions show substantial reductions in failure types of time limit, memory limit, and compilation errors. However, runtime errors. although somewhat reduced, do not experience as pronounced a decline, highlighting persistent challenges in edgecase handling and execution robustness. We hypothesize that one possible reason top-performing models still exhibit relatively high runtime error rates could be their tendency to pursue more aggressive and optimized coding patterns, such as employing custom data structures, in-place transformations, and pointer arithmetic. These advanced techniques,

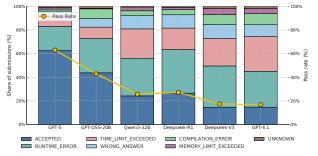

Figure 4: Submission status distribution for six selected models. The models are sorted based on performance from left to right. Solutions by stronger reasoning models show substantial reductions in failure types of time limit, memory limit, and compilation errors.

while algorithmically sound, might inherently increase the potential for execution faults⁶, especially in edge scenarios. Interestingly, GPT-OSS-20B displays compilation error rates comparable to weaker, non-reasoning-intensive models. We attribute this unexpected result to its cautious approach: the model often declines to generate solutions when it anticipates insufficient reasoning time, thereby

⁶For instance, a simple algorithm like summing elements of an array becomes significantly more complex when highly optimized for memory access patterns using techniques such as loop unrolling and pragma directives in C++ (e.g., #pragma omp simd, #pragma unroll).

triggering compilation-related failures. These findings highlight a limitation in the reinforcement learning approaches employed by current models (DeepSeek-AI et al., 2025; Yang et al., 2025b), which predominantly use solution correctness as the sole reward, neglecting efficiency and memory management. Future training techniques could incorporate fine-grained reward signals targeting these attributes, enabling models to optimize not only for correctness but also for reliable and efficient code execution.

6 CONCLUSION

In this work, we propose LiveOIBench, a comprehensive competitive coding benchmark featuring expert-curated OI-style tasks with detailed subtask rubrics, direct comparisons to human contestant performance, continuous updates with new Olympiad tasks to prevent contamination, and an offline evaluation system ensuring accessible and reproducible assessments. We extensively evaluate 32 models including both proprietary and open-weight models. Our results highlight that proprietary models, particularly GPT-5, achieve impressive results but fall short of top human contestants, who typically place above the 90th percentile. Among open-weight models, GPT-OSS, Seed-OSS, and Qwen-3-32B demonstrate significant progress, with GPT-OSS-120B notably narrowing the performance gap to proprietary alternatives. Further analyses reveal that current models particularly struggle with advanced algorithmic tasks, such as dynamic programming. Additionally, our reasoning trace analysis indicates that robust model performance relies on strategically allocating exploratory and analytical reasoning behaviors. Lastly, we find stronger models reduce common failures yet persistently face runtime errors due to optimized coding techniques, suggesting refined training for efficiency and memory management. Moving forward, we envision leveraging this benchmark to further investigate inference-time scaling strategies and training methods, particularly for challenging reasoning tasks. By offering a rigorous, reproducible, and continuously updated evaluation benchmark, LiveOIBench aims to drive significant advancements in the reasoning and coding capabilities of LLMs.

A DATASET CONSTRUCTION

A.1 TASK COLLECTION

We identified multiple Informatics Olympiad competitions and gathered all contests held from 2023 onward, along with their official website information. We specifically focused on the post-2022 period to minimize potential contamination from model training data. In total, we collected 72 contests, 46 of which include results from human contestants. The detailed statistics can be found in Table A4 and Table A5.

Contest Information Extraction: We developed a dedicated web crawler for each competition to extract task information directly from its official website. This includes task statements, test cases,

reference and unofficial solutions, code attachments, time and memory limits, and detailed subtask specifications. We also parsed the contestant results pages and reformatted them into standardized CSV files. To do this, we copied the raw webpage content into Gemini-2.5-Pro and prompted it to generate CSVs with normalized headers. Each file captures contestant names, countries, total and per-task scores, and awarded medals. After manual verification against the official data, we integrated the processed results into our contestant database. After integrating contestant results into our database, we determined medal thresholds as follows. For general contests, the Gold, Silver, and Bronze thresholds are defined by the lowest total scores among participants who received each respective medal. In contrast, for the USACO Bronze, Silver, and Gold contests, thresholds correspond to the minimum scores required to advance to the next competition level. In the case of the USACO Platinum contest, thresholds are based solely on the number of problems solved: solving exactly one problem earns a Bronze medal, two problems earn Silver, and solving more than two problems earns Gold.

Missing Data: When the official website lacks complete or up-to-date contest information, we enhance our dataset by retrieving the missing details from reputable secondary platforms such as CSES and LibreOJ. These platforms host curated repositories of contest materials and metadata, and contain a substantial amount of user submissions along with their corresponding pass rates. Their widespread adoption within the competitive programming and informatics communities suggests high accuracy and reliability. For contests missing test cases on the official site, we employ a parser to retrieve them from CSES and integrate them into our dataset. If official code solutions are absent or invalid, we obtain five user-submitted solutions from LibreOJ that achieved a 100% pass rate and include them in the dataset. Valid solutions from open-source Github repositories are also downloaded to enhance the dataset. By supplementing incomplete primary data with these established sources, we ensure our dataset maintains high standards of accuracy and completeness.

A.2 Problem Filtering and Solution Verification

To ensure that the solutions collected from official websites and external platforms are accurate, we create an evaluation code judge to validate whether our solution can pass all the test cases from our dataset. The code judge operates differently based on the question type. If a question is removed from a contest, we exclude it from the analysis when comparing model scores against human performance.

Batch: For all the batch problems, we run the official code solution against the input-output test cases. The input file is provided to the program, and the code output is verified against the expected output. The subtask scores are computed to verify that the total score adds up to the total points. Any problem for which the solution failed a test case or produced an invalid total score was excluded from further analysis. For problems that accept multiple valid outputs, we set up a testing environment using the grader file supplied in the contest materials and apply the same evaluation procedure, disregarding problems with incorrect solution files.

Interactive: If the problem type is interactive, the grader file is executed first to establish the testing environment. Subsequently, the solution file is launched within the environment to exchange input/output streams interactively. After the problem finishes, the grader's evaluation output is collected to determine whether the solution passed. If the grader doesn't return a full mark on the ground-truth solution, the corresponding problem is discarded.

Output-Only: We exclude output-only problems since they don't require contestants to submit algorithmic code solutions, making them difficult for evaluating model performance.

A.3 METADATA COLLECTION

To further enrich and structure our dataset, we augment it with comprehensive problem metadata crawled from solved.ac and Luogu , capturing difficulty ratings and algorithm tags. We then utilize Gemini-2.0-Flash to semantically match problems across different platforms, resolving inconsistencies in label formats and taxonomies through a unified mapping strategy.

Difficulty Tags: Solved.ac uses integer values from 1 to 30 to represent the difficulty levels, where 1 corresponds to the easiest tier (Bronze V) and 30 corresponds to the hardest tier (Ruby I). However, Luogu employs 7 categorical text labels for its difficulty. To reconcile the inconsistent difficulty scales across platforms, we construct a numerical mapping on a 0-30 scale for Luogu, translating

the native difficulty descriptor tags into standardized numerical scores using the mapping as specified in Table A1. The unified scale enables us to assign difficulty scores to all problems by taking the union of both sources.

Difficulty Tag	Difficulty Score
Beginner	5
Easy	9
Intermediate	13
Hard	16
Advanced	18
Expert	21
Master	24

Table A1: Difficulty Tags and Corresponding Scores

Algorithm Tags. To ensure data integrity and consistency, we develop a normalization dictionary to standardize dataset labels. This dictionary systematically resolves lexical and semantic variations, including synonyms, related terms, and differences in granularity, by mapping them to a unified set of canonical tags.

Missing Tags. In cases where tags were missing, we utilize Gemini-2.0-Flash to infer plausible labels and difficulty from the problem description, enhancing both completeness and labeling quality. To assess the reliability of LLM-inferred difficulty scores, we conduct sampling-based validation on problems with existing difficulty annotations and observe a high degree of consistency with their original scores.

Divisions. Finally, we analyze the distribution of algorithm and difficulty tags across the corpus and partition the difficulty range of all contests into four divisions, thereby improving robustness and facilitating downstream contest categorization. The division boundaries are listed in Table A2.

Division	Min Difficulty	Max Difficulty	Avg Difficulty	Total Contests
Division 4	5.0	15.78	13.76	17
Division 3	16.0	20.33	18.05	19
Division 2	20.33	22.33	21.52	19
Division 1	22.5	30.0	23.62	17

Table A2: Division Boundaries by Difficulty

Problem Difficulty. We sort all task difficulty scores and split them into three equal-sized buckets by taking the empirical one-third and two-thirds cut points. The problem difficulty distribution is listed in Table A3

Table A3: Problem difficulty distribution using quantile thresholds.

Level	# Problems	% of Total	Threshold Rule
Easy	143	35.48%	$d \le 17$
Medium	144	35.73%	$18 \le d \le 22$
Hard	116	28.78%	$d \ge 23$
Total	403	100%	_

A.4 CODEFORCES RATINGS COLLECTION

Result Collection: For each contest, the raw human results files are downloaded and restructured. These files typically include contestant identifiers such as usernames, countries, individual task scores, total scores, and medal information.

Rating Data Retrieval: Codeforces rating data are obtained by algorithmically mapping contestants' names to their corresponding profiles in the Codeforces database. Usernames are first normalized by removing diacritics and converting all text to lowercase to enhance matching robustness. Using these normalized usernames together with each contestant's country, our program submits Google Search queries and inspects the top results to identify potential Codeforces profile URLs. When valid

Codeforces URLs are identified, the extracted handles are queried via the Codeforces API to obtain detailed user profile information, including full name, country, Codeforces ID, and rating history.

Database Generation: The retrieved rating histories are parsed to extract Codeforces ratings for each year from 2022 to 2025. When annual data are unavailable, we backfill missing entries by using contestants' most recent available Codeforces ratings from prior years. For instance, if a contestant participates in 2025 but lacks an updated rating, we use their previous rating when applicable. Contest names and contestant metadata are then appended to a master Codeforces database. If a contestant's record already exists, only new contest information is added to the existing profile.

Rating Matching: After these procedures are applied to every contest results file, a database of Codeforces ratings for all contestants is established. Finally, we link each contestant's Codeforces rating—matched by name and country—to the corresponding contest year.

Model Ratings: To benchmark model performance on our dataset, we calculate a corresponding Codeforces rating for each model on every contest. For each task, we present the full problem statement to the models and prompted them to generate code solutions. Using the provided subtask and test-case data, we compute the total score of each model's solution. Once total scores were obtained, we derive Codeforces ratings for the models using the CodeElo formula (Quan et al., 2025) given below, where m is the expected rank of a contestant (or model) with rating r, compared to n contestants with known Codeforces ratings $r_{(i)}$.

$$m = \sum_{i=1}^{n} \frac{1}{1 + 10^{\frac{r-r_{(i)}}{400}}}$$

To ensure the reliability and accuracy of our analysis, we perform several filtering steps on the human data prior to computing Elo ratings. First, we exclude participants who either lack an official Codeforces rating or whose ratings fall below 500. Next, we identify and remove performance outliers by fitting a third-degree polynomial regression to the score-rating data and discarding any results lying more than 2 standard deviations from the fitted curve.

Finally, to reduce statistical noise and further enhance data quality, we exclude contests with fewer than 15 valid human Codeforces ratings from the Elo calculation. These steps collectively ensure that our resulting model ratings reliably reflect the true relationship between contestants' Codeforces ratings and their total contest scores. Table A6 presents all contests for which we successfully matched contestants to their Codeforces profiles, along with the median Codeforces rating for each contest.

Competitions	Total Tasks	Total Contests	Avg. Subtasks	Test Cases/Task	Token Count	Difficulty
IOI	12	2	7.08	112.42	2359.58	22.83

A.5 SAMPLE TASK

We now present an example drawn from the *International Olympiad in Informatics 2024*. The following task, titled *Nile*, illustrates a typical problem style in our dataset.

Problem: Nile

You want to transport N artifacts through the Nile. The artifacts are numbered from 0 to N-1. The weight of artifact i ($0 \le i < N$) is W[i].

To transport the artifacts, you use specialized boats. Each boat can carry **at most two** artifacts.

- If you decide to put a single artifact in a boat, the artifact weight can be arbitrary.
- If you want to put two artifacts in the same boat, you have to make sure the boat is balanced evenly. Specifically, you can send artifacts p and q ($0 \le p < q < N$) in the same boat only if the absolute difference between their weights is at most D, i.e. $|W[p] W[q]| \le D$.

The cost of transporting artifact i ($0 \le i < N$) is:

- A[i], if you put the artifact in its own boat, or
- B[i], if you put it in a boat together with some other artifact.

If artifacts p and q are sent together, the total cost is B[p] + B[q]. Since B[i] < A[i] for all i, sending an artifact with another is always cheaper when possible.

Unfortunately, the river is unpredictable and the value of D changes often. Your task is to answer Q queries, described by array E of length Q. For query j $(0 \le j < Q)$, the answer is the minimum cost of transporting all N artifacts when D = E[j].

Implementation Details

```
std::vector<long long> calculate_costs(
    std::vector<int> W,
    std::vector<int> A,
    std::vector<int> B,
    std::vector<int> E)
```

- W, A, B: arrays of length N, describing weights and costs.
- E: array of length Q, values of D.
- Returns: array R with R[j] equal to the minimum cost for D = E[j].

Constraints

```
\begin{split} &1 \leq N \leq 100,\!000 \\ &1 \leq Q \leq 100,\!000 \\ &1 \leq W[i] \leq 10^9 \text{ for each } i \text{ such that } 0 \leq i < N \\ &1 \leq B[i] < A[i] \leq 10^9 \text{ for each } i \text{ such that } 0 \leq i < N \\ &1 \leq E[j] \leq 10^9 \text{ for each } j \text{ such that } 0 \leq j < Q \end{split}
```

Subtasks

Subtask	Score	Additional Constraints
1	6	$Q \le 5$; $N \le 2000$; $W[i] = 1$ for each i such that $0 \le i < N$
2	13	$Q \leq 5$; $W[i] = i + 1$ for each i such that $0 \leq i < N$
3	17	$Q \le 5$; $A[i] = 2$ and $B[i] = 1$ for each i such that $0 \le i < N$
4	11	$Q \le 5; N \le 2000$
5	20	$Q \leq 5$
6	15	$A[i] = 2$ and $B[i] = 1$ for each i such that $0 \le i < N$
7	18	No additional constraints.

Example

Explanation:

- D = 5: pair (0,3), others alone $\Rightarrow 16$
- D = 9: pairs (0,1) and (2,3), artifact 4 alone $\Rightarrow 11$

```
• D=1: no pairs possible, all alone \Rightarrow 23

Sample Grader

Input format:

N

W[0] A[0] B[0]
W[1] A[1] B[1]
...
W[N-1] A[N-1] B[N-1]
Q
E[0]
E[1]
...
E[Q-1]
Output format:
R[0]
R[1]
...
R[S-1]
where S=Q is the length of the output array.
```

```
#include "nile.h"
#include <cstdio>
#include <vector>

int main() {
   int N; scanf("%d", &N);
   std::vector<int> W(N), A(N), B(N);
   for (int i = 0; i < N; i++)
        scanf("%d%d%d", &W[i], &A[i], &B[i]);
   int Q; scanf("%d", &Q);
   std::vector<int> E(Q);
   for (int j = 0; j < Q; j++)
        scanf("%d", &E[j]);

auto R = calculate_costs(W, A, B, E);
   for (auto x : R) printf("%lld\n", x);
}</pre>
```

A.6 COMPETITION INFORMATION

International Olympiad in Informatics (IOI) First held in 1989, the IOI is the annual world championship for informatics. Participants are organized into national delegations, with each of the approximately 90 participating countries sending a team of up to four students. These contestants are selected through highly rigorous, multi-stage national olympiads.

Baltic Olympiad in Informatics (BOI) Established in 1995, the BOI brings together teams from countries bordering the Baltic Sea and invited guest nations. Each member country's national informatics organization selects a team of their top-ranking secondary school students, who are often candidates for that year's IOI team.

Central European Olympiad in Informatics (CEOI) Originating in 1994, the CEOI is an onsite competition for teams from Central European member countries and several guest nations. Delegations are chosen by respective national olympiad committees and are typically composed of students who have achieved top results in their national contests.

European Girls' Olympiad in Informatics (EGOI) An initiative from 2021, the EGOI is an international competition for teams from European and guest countries. Each participating country selects a team of up to four female secondary school students who have demonstrated strong performance in their national-level informatics competitions.

European Junior Olympiad in Informatics (EJOI) Founded in 2017, the EJOI is a major international event for a younger age group. Each European member country sends a national delegation of up to four students who are under the age of 15.5. Participants are typically the winners of national junior-level informatics olympiads.

International Advanced Tournament in Informatics (IATI) Established in 2009 and hosted in Shumen, Bulgaria, the IATI is an international competition with two distinct age divisions, Junior and Senior. It brings together national and regional teams from numerous participating countries. Contestants are typically selected by their national informatics organizations based on strong results in previous competitions.

Open Olympiad in Informatics (OOI) The Open Olympiad in Informatics (OOI) is the final stage of the All-Russian Olympiad in Informatics. Its participants are composed of two groups: the top Russian students who have advanced through a rigorous nationwide selection process, and official teams from various guest countries that receive a formal invitation to compete.

Romanian Master of Informatics (RMI) First held in 2009, the RMI is a prestigious international competition. Participation is by invitation only; the organizers invite official national teams from countries with a strong track record at the IOI. This makes the participant pool one of the strongest in the world.

Asia-Pacific Informatics Olympiad (APIO) The APIO, an online contest since 2007, involves students from countries and regions across the Asia-Pacific. Each member region organizes its own contest to select a set of national participants, who then compete from a supervised site within their home country.

Japanese Olympiad in Informatics (JOI) Since 1994, the JOI has served as Japan's national selection process. It is open to Japanese junior high and high school students, who compete in preliminary rounds. Top performers are then invited to an exclusive on-site final and training camp, from which the IOI team is chosen.

Canadian Computing Olympiad (CCO) The CCO, since 1996, is the invitational final stage of Canada's national selection process. Participation is granted to the top 20-25 senior-level students from the open Canadian Computing Competition (CCC), who then compete to form the four-member IOI team.

Croatian Open Competition in Informatics (COCI) Since 2006, COCI has operated as an online contest series open to individual participants worldwide. For Croatian students, cumulative performance across the year's rounds is a primary component in the selection process for the national team for the IOI and other international events.

Nordic Olympiad in Informatics (NOI) The Nordic Olympiad in Informatics brings together top secondary school students from Denmark, Finland, Iceland, Norway, and Sweden. Each country selects its participants based on the results of their respective national olympiads, with the NOI serving as a key qualifier for the BOI.

USA Computing Olympiad (USACO) The USACO is an open competition primarily for precollege students in the United States, though it attracts many international participants. Its monthly online contests determine which top US-based students in the Platinum division are invited to a training camp, where the four-member IOI team is selected.

B MODEL INFORMATION

- **Proprietary LLMs:** This category includes high-performing proprietary models such as Gemini-2.5 (Comanici et al., 2025), GPT-o3-Mini-High (OpenAI, 2025c), and GPT-4.1 (OpenAI, 2025a).
- Open-weight Thinking LLMs: These are openly available models that are empowered with inherent thinking or reasoning capabilities. This group includes Qwen3 (Yang et al., 2025b) and DeepSeek-R1 (DeepSeek-AI et al., 2025), as well as those distilled from DeepSeek-R1.
- Open-weight Non-Thinking LLMs: This category consists of openly available models that are not equipped with intrinsic thinking mechanisms. This includes DeepSeek Coder-V2 (DeepSeek-AI et al., 2024b), DeepSeek-V3 (DeepSeek-AI et al., 2024a), Qwen2.5 (Yang et al., 2024), Qwen2.5-Coder (Hui et al., 2024), Qwen3 (Yang et al., 2025a), Mistral (Jiang et al., 2023) and Llama-3 (Dubey et al., 2024).
- Refer to Table A7 and Table A8 for more details.

Table A7: Model list of Non-Thinking LLMs with model providers

Non-Thinking LLMs	Model Provider
GPT-4.1 (OpenAI, 2025a)	OpenAI
Qwen2.5-72B (Yang et al., 2024)	Alibaba

DeepSeek-R1-Distill-Llama-8B (DeepSeek-AI et al., 2025)	DeepSeek	32k

C EVALUATION METRICS

- Pass@k (Kulal et al., 2019; Chen et al., 2021): We use the conventional Pass@k, which measures the fraction of problems for which at least one of the k generated solutions is correct. We use k=8.
- **Relative Score:** This metric is defined as the division of the model's score over the total possible score of a contest, providing a normalized measure of performance.
- Average Percentile: To benchmark LLM performance against human capabilities, we map the models' scores to a percentile rank based on the performance distribution of human contestants.
- Olympics Medal System: It uses the authoritative cutoffs in the Olympiads to decide if a model's performance is qualified for a medal (gold, silver, or bronze).
- Codeforces ELO: Inspired by the widely used rating system in competitive programming, we treat each model as a "virtual contestant" and update its rating after every contest based on its relative standing against human participants.

D FULL RESULTS

We present the complete evaluation results of all models on LiveOIBench. Table A9 provides the overall leaderboard across all 72 contests, while Table A10 breaks down performance by contest tags. Finally, Figure A1 shows a screenshot of the LiveOIBench website, which allows users to interactively explore model performances by selecting specific contest ranges.

E ADDITIONAL ANALYSIS

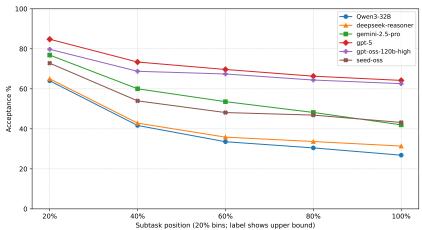

Figure A2: Mainstream model performance over sub-task positions. As expected, later subtasks pose greater challenges for LLMs to tackle.

E.1 MODEL PERFORMANCE ACROSS YEARS

Figure A3 shows quarterly pass rates of four mainstream LLMs from Q4'22 to Q2'25. The performance trends are broadly similar across models: all experience an early decline in 2023, recover through 2024, peak around late 2024 to early 2025, and then drop again in Q2'25. Importantly, there is no sharp bump or drop around the knowledge cutoff, suggesting that these models are not facing

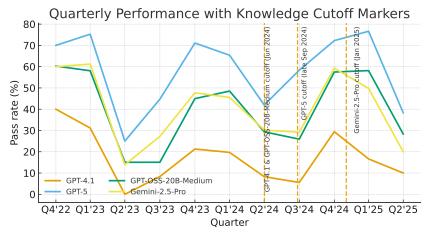

Figure A3: Mainstream model performance over quarters. This plot shows consistent performance trend among select models and confirms no data contamination in mainstream LLMs.

significant data contamination issues. Quantitatively, GPT-5 consistently leads: in its stronger quarters (Q1'23, Q4'23, Q1'25), it consistently outperforms Gemini-2.5-Pro and GPT-OSS-20B-Medium by about 15–25 percentage points, which is in line with Table A9.

E.2 INFERENCE-TIME SCALING

Inference-time scaling has been shown effective for improving model performance in math (Snell et al., 2024; Brown et al., 2024) and coding (Li et al., 2025a; Ehrlich et al., 2025) domains. We investigate two dimensions: *parallel scaling* involves sampling multiple diverse solution candidates (Chen et al., 2021; Jain et al., 2024), while *sequential scaling* generates long chains-of-thought with complex reasoning strategies such as self-reflection and backtracking (DeepSeek-AI et al., 2025).

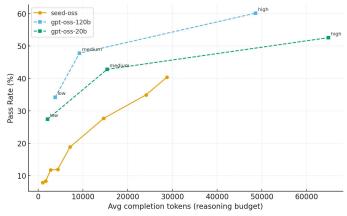

Figure A4: **Sequential Scaling** plots the pass rate against the reasoning budget (measured in average completion tokens), showing that performance improves with more extensive reasoning, though models exhibit different token efficiencies.

Parallel Scaling: GPT-5 demonstrates superior coding capacity boundary. Figure 2 reveals significant differences in coding capacity boundaries (Yue et al., 2025) across models as measured by Pass@k. GPT-5 could pass around 64% of the problems given 8 attempts per problem. The steepest improvements occur between Pass@1 and Pass@4, indicating that the marginal benefit of additional attempts diminishes rapidly as models approach their capacity limits (Kulal et al., 2019). The persistent performance gaps between proprietary and open-source models across all sampling levels suggest fundamental differences in maximum coding capability rather than artifacts of insufficient attempts (Li et al., 2022b; Hendrycks et al., 2021a).

Sequential Scaling: Reasoning models benefit from additional reasoning token budget. Figure A4 shows pass rates improving as token budget increases across all three models. GPT-OSS-120B achieves the highest performance with the fewest tokens generated. A key insight emerges: smaller models can approach larger model performance with sufficient reasoning budget, suggesting a practical trade-off for resource-constrained practitioners who may prefer specialized smaller models over large ones.

Both scaling approaches provide complementary benefits but face efficiency limitations. Sequential scaling shows promise for complex algorithmic problems but requires substantial computational resources, while parallel scaling reveals each model's performance ceiling as improvements plateau with additional samples (Chen et al., 2021; Austin et al., 2021). Future work could focus on developing hybrid approaches that combine both scaling paradigms while reducing computational overhead.

E.3 REASONING BEHAVIORS ANALYSIS

As described in Section 5.2, we partition each reasoning trace into segments of approximately 5k tokens, estimated by dividing the total token length by four. We categorize models' reasoning traces into eight behaviors, which we group into five broader categories: **Analysis** (Algorithm/Proof Analysis, Complexity Analysis), **Planning** (Problem Restatement, Subgoal Setting), **Exploration** (Backtracking, Dead-end Recognition), **Implementation** (Pseudo Implementation), and **Validation** (Test Case Verification).

The following prompts were used to elicit and analyze these reasoning behaviors of each segment:

- PR_PROMPT \rightarrow Problem Restatement (Planning). See Prompt 1.
- CMP_PROMPT \to Complexity Analysis (Analysis). See Prompt 2.
- VT_PROMPT \rightarrow Test Case Verification (Verification). See Prompt 3.
- SUB_PROMPT \rightarrow Subgoal Setting (Planning). See Prompt 4.
- DED_PROMPT \to Dead-end Recognition (Exploration). See Prompt 5.
- BKT_PROMPT \rightarrow Backtracking (Exploration). See Prompt 6.
- AP_PROMPT \rightarrow Algorithm/Proof Analysis (Analysis). See Prompt 7.
- PSD_PROMPT \rightarrow Pseudo Implementation (Implementation). See Prompt 8.

```
PR PROMPT = """
You are an auditor. Count occurrences of the behavior PR (Problem
   Restatement) in a competitive-programming reasoning trace.
DEFINITION (apply strictly)
PR = Expressing the task in the solver's own words to clarify WHAT
   must be computed/decided/constructed (not HOW).
Include: restating the goal/output/validity conditions; clarifying
   what constitutes a correct answer.
- Count 1 per PR-labeled step.
OUTPUT (strict JSON ONLY -- no extra text):
  "PR": <integer count>,
  "events": [
    {"snippet": "<short quote>", "reason": "<why it matches PR>"}
}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of PR.
```

Prompt 1: PR_PROMPT (Problem Restatement)

```
CMP_PROMPT = """
You are an auditor. Count occurrences of the behavior CMP (Complexity
   Analysis) in a competitive-programming reasoning trace.
DEFINITION
CMP = Analyzing asymptotic time/space complexity and feasibility
   versus constraints.
COUNT
- Count 1 per CMP-labeled step.
OUTPUT (strict JSON ONLY):
 "CMP": <integer count>,
 "events": [
   {"snippet": "<short quote>", "reason": "<why it matches CMP>"}
}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of CMP.
```

Prompt 2: CMP_PROMPT (Complexity Analysis)

```
VT_PROMPT = """
You are an auditor. Count occurrences of the behavior V-T (Test Cases
   Verification) in a competitive-programming reasoning trace.
DEFINITION
V-T = Checking the method on specific inputs and comparing with
   expected/reference outcomes.
Include: "On sample 2, expected=5, we get 5"; "Fails on [3,3,2] with
   output 7".
- Count 1 per V-T-labeled step (multiple tests in one step = 1).
OUTPUT (strict JSON ONLY):
  "V-T": <integer count>,
 "events": [
   {"snippet": "<short quote>", "reason": "<why it matches V-T>"}
}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of V-T.
```

Prompt 3: VT_PROMPT (Test Case Verification)

```
SUB_PROMPT = """
You are an auditor. Count occurrences of the behavior SUB (Subgoal
   Setting) in a competitive-programming reasoning trace.
DEFINITION
SUB = Breaking the solution into intermediate objectives or a
   checklist before implementation.
Include: ordered lists like "parse -> preprocess -> compute -> output
   "; milestones like "build graph; find components; count sizes".
COUNT
- Count 1 per SUB-labeled step.
OUTPUT (strict JSON ONLY):
  "SUB": <integer count>,
 "events": [
   {"snippet": "<short quote>", "reason": "<why it matches SUB>"}
 1
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of SUB.
```

Prompt 4: SUB_PROMPT (Subgoal Setting)

```
DED_PROMPT = """
You are an auditor. Count occurrences of the behavior DED (Dead-end
   recognition) in a competitive-programming reasoning trace.
DEFINITION
DED = Explicitly concluding the current approach is incorrect/
   insufficient or cannot meet constraints.
Include: naming a failure mode ("greedy not optimal", "breaks for
   duplicates", "TLE for n=2e5").
COUNT
- Count 1 per DED-labeled step.
OUTPUT (strict JSON ONLY):
  "DED": <integer count>,
  "events": [
    {"snippet": "<short quote>", "reason": "<why it matches DED>"}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of DED.
```

Prompt 5: DED_PROMPT (Dead-end Recognition)

```
BKT_PROMPT = """
You are an auditor. Count occurrences of the behavior BKT (
   Backtracking) in a competitive-programming reasoning trace.
DEFINITION
BKT = Revising or replacing the plan after recognizing a failure/
   limitation.
Include: "scrap/switch/replace", "instead we will...", "new plan: ..."
COUNT
- Count 1 per BKT-labeled step.
OUTPUT (strict JSON ONLY):
  "BKT": <integer count>,
  "events": [
    {"snippet": "<short quote>", "reason": "<why it matches BKT>"}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of BKT.
{TRACE}
11 11 11
```

Prompt 6: BKT_PROMPT (Backtracking)

```
AP_PROMPT = """
You are an auditor. Count occurrences of the behavior AP (Algorithm /
   Proof analysis) in a competitive-programming reasoning trace.
DEFINITION
AP = Justifying WHY the chosen algorithm/structure is correct/
   appropriate (proof sketches, invariants used as correctness
   arguments, reductions implying correctness).
Include: exchange/optimality arguments, loop-invariant proofs,
   reductions with correctness justification, structural reasoning
   that ensures the property.
- Count 1 per AP-labeled step.
OUTPUT (strict JSON ONLY):
  "AP": <integer count>,
  "events": [
   {"snippet": "<short quote>", "reason": "<why it matches AP>"}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of AP.
{TRACE}
```

Prompt 7: AP_PROMPT (Algorithm/Proof Analysis)

```
PSD_PROMPT = """
You are an auditor. Count occurrences of the behavior PSD (Pseudo
   implementation) in a competitive-programming reasoning trace.
DEFINITION
PSD = Presenting the algorithm as structured steps or pseudocode with
   control flow, without full code.
Include: numbered/indented outlines; loops/ifs; while/for; state
   updates in an algorithmic outline.
COUNT
- Count 1 per PSD-labeled step.
OUTPUT (strict JSON ONLY):
  "PSD": <integer count>,
  "events": [
    {"snippet": "<short quote>", "reason": "<why it matches PSD>"}
<TRACE>
{TRACE}
</TRACE>
Analyze the trace and count the occurrences of PSD.
{TRACE}
```

Prompt 8: PSD_PROMPT (Pseudo Implementation)

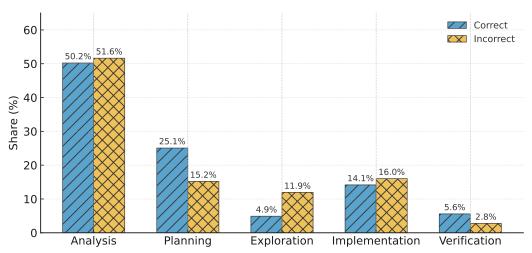

Figure A5: The reasoning behaviors of GPT-OSS-120B-High on easy problems across correct and incorrect solutions. Plan and verification behaviors are still important for models to produce correct solutions.

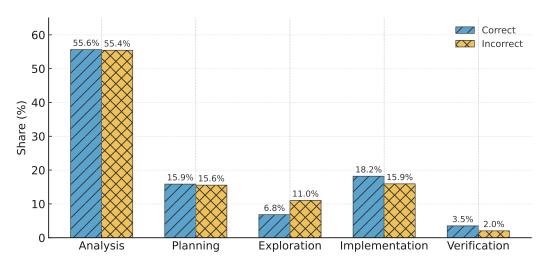

Figure A6: The reasoning behaviors of GPT-OSS-120B-High on medium problems across correct and incorrect solutions. Similar to easy problems, there is less exploration and more verification behaviors for correct solutions.

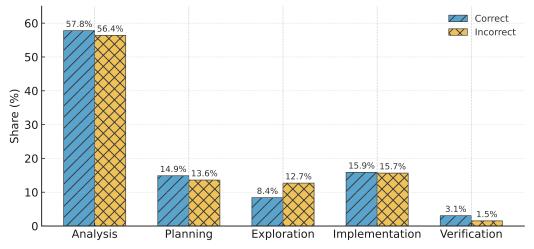

Figure A7: The reasoning behaviors of GPT-OSS-120B-High on hard problems across correct and incorrect solutions. Analysis, plan, and verification behaviors are still important for models to produce correct solutions.

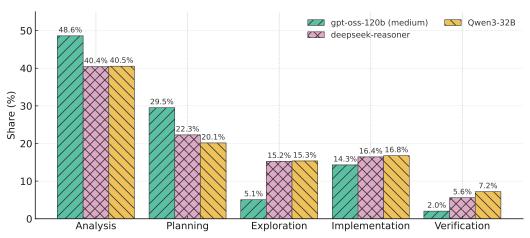

Figure A8: The reasoning behaviors of models producing correct solutions. Stronger reasoning models reduce unnecessary exploration, dedicating more resources to planning, structured analysis, and solution development.
